Humans, or rather *Homo sapiens*, are the most detrimental invasive species on earth. Modern humans first appeared around 200,000 years ago, and have since evolved traits useful in surviving different environments and outcompeting almost any other organism. As seen in this picture, humans have preserved natural environments such as this that contain rare spectacles like us, but these environments are never truly natural. With an increase in tourism comes an increase of human impacts. Roads create habitat fragmentation and cars create pollution, just a few of many disturbances humans cause. Humans have adapted to their environment over thousands of years, learning to build shelters in cold climates with advanced technology, altering their diet by growing crops or drinking milk, and even evolving to breathe well in high elevations. Because the human population has been growing exponentially, it has become harmful to their own health, as seen with the effects of climate change. A solution that China came up with to manage the species was the one child policy, although this is no longer in effect, and there have been few alternative methods to managing this invasive species.
